S. Dhanush

2 PM to 4 PM

1. Requirements it is the way of making the application to solve a problem. The requirement is given by the client to make the user to be done their work. There are three types of requirements.

- * Functional requirements

- * Non-functional requirements

- * Domain requirements

Functional Requirements

It is the requirements that trace the flow of the application with the core functions given by the client.

User Authentication: It is the function which will make the login of valid user.

Track & Evaluation:

These can be made to function the application which will not block the flow of application.

non-functional requirements :-

It is the process of finding the performance of the application that are made find the quality of the applications

usability :- It is made to the userfriendly

~~scalability~~ Scalability :- the uptime should be 99.99 times

Capability :- the application can check the number of users like 1,000 to be the limit

2. Boundary Value Analysis :-

It is the way of Equilant Partitioning that will make the valid and Invalid of the value with the Boundary

Test value :-

the value that is given in the range of data in the function.

maximum Boundary :-

the maximum value from the range to the one valid and two invalid data in the Boundary.

minimum boundary :-

It is the range value to the ~~the~~ function data which is done to be the one valid and invalid of the data in function

Bvm example :-

invalid	Valid	invalid
$\text{min} - 1$	$\text{min} + 1, \text{max} + 1, \text{nominal}$	$\text{max} + 1$
17	18, 19, 37, 58, 59	60
